

MODULE FMZM_1

USE FMVALS, ONLY : MULTI, FM, IM, ZM

! FMZM 1.4 David M. Smith

! This module extends the definition of the basic Fortran arithmetic and function operations so they also apply to multiple precision numbers, using version 1.3 of FM.

! There are three multiple precision data types:

! FM (multiple precision real)
! IM (multiple precision integer)
! ZM (multiple precision complex)

! For some examples and general advice about using these multiple-precision data types, see the program SampleFM.f95.

! Most of the functions defined in this module are multiple precision versions of standard Fortran functions. In addition, there are functions for direct conversion, formatting, and some mathematical special functions.

! TO_FM is a function for converting other types of numbers to type FM. Note that TO_FM(3.12) converts the REAL constant to FM, but it is accurate only to single precision, since the number 3.12 cannot be represented exactly in binary and has already been rounded to single precision. Similarly, TO_FM(3.12D0) agrees with 3.12 to double precision accuracy, and TO_FM('3.12') or TO_FM(312)/TO_FM(100) agrees to full FM accuracy.

! TO_IM converts to type IM, and TO_ZM converts to type ZM.

! Functions are also supplied for converting the three multiple precision types to the other numeric data types:

! TO_INT converts to machine precision integer
! TO_SP converts to single precision
! TO_DP converts to double precision
! TO_SPZ converts to single precision complex
! TO_DPZ converts to double precision complex

! WARNING: When multiple precision type declarations are inserted in an existing program, take care in converting functions like DBLE(X), where X has been declared as a multiple precision type. If X was single precision in the original program, then replacing the DBLE(X) by TO_DP(X) in the new version could lose accuracy. For this reason, the Fortran type-conversion functions defined in this module assume that results should be multiple precision whenever inputs are. Examples:

! DBLE(TO_FM('1.23E+123456')) is type FM
! REAL(TO_FM('1.23E+123456')) is type FM
! REAL(TO_ZM('3.12+4.56i')) is type FM = TO_FM('3.12')
! INT(TO_FM('1.23')) is type IM = TO_IM(1)
! INT(TO_IM('1E+23')) is type IM
! CMLX(TO_FM('1.23'),TO_FM('4.56')) is type ZM

! IS_OVERFLOW, IS_UNDERFLOW, and IS_UNKNOWN are logical functions for checking whether a multiple precision number is in one of the exception categories. Testing to see if a type FM number is in the +overflow category by directly using an IF can be tricky. When MAFM is +overflow, the statement

! IF (MAFM == TO_FM(' +OVERFLOW ')) THEN
! will return false, since the comparison routine cannot be sure that two different overflowed results would have been equal if the overflow threshold had been higher. Instead, use
! IF (IS_OVERFLOW(MAFM)) THEN

! which will be true if MAFM is + or - overflow.

! Programs using this module may sometimes need to call FM, IM, or ZM routines directly. This
! is normally the case when routines are needed that are not Fortran intrinsics, such as the
! formatting subroutine FM_FORM. In a program using this module, suppose MAFM has been declared
! with TYPE (FM) :: MAFM. To convert the number to a character string with F65.60 format, use
! CALL FM_FORM('F65.60',MAFM,ST1)

! WARNING: To be safe, all multiple precision variables in a user's program should be declared
! as type (FM), (IM), or (ZM), and any direct calls to subroutines should be the kind
! with the underscore. Subroutines that define one or more multiple precision output
! values, such as computing pi using
! CALL FM_PI(PI)
! automatically cause PI to be put into the FM saved variable area of storage. Calling
! the low-level routine (CALL FMPI(PI%MFM)) would cause PI to be treated as an FM
! temporary variable if PI had not been previously defined in the program. Then the
! value of PI could be discarded before the program is finished using it.

! In subroutine or function subprograms all multiple precision variables that are local to that
! routine should be declared with the SAVE attribute. It is not an error to omit SAVE, but if
! the compiler creates new copies of the variables for each call to the routine, then the program
! will leak memory.

! Type (FM), (IM), or (ZM) variables cannot have their multiple precision values initialized in
! the declaration statement, as can ordinary variables. If the original program had

```
! DOUBLE PRECISION :: X = 2.3D0  
! then the corresponding FM version would have  
! TYPE (FM), SAVE :: X  
! ... (other declarations) ...  
! X = TO_FM( '2.3' )  
!
```

! An attempt to use a multiple precision variable that has not been defined will be detected by
! the routines in this module and an error message printed.

! For each of the operations =, ==, /=, <, <=, >, >=, +, -, *, /, and **, the interface
! module defines all mixed mode variations involving one of the three multiple precision derived
! types and another argument having one of the types: { integer, real, double, complex, complex
! double, FM, IM, ZM }. So mixed mode expressions such as

```
! MAFM = 12  
! MAFM = MAFM + 1  
! IF (ABS(MAFM) > 1.0D-23) THEN  
! are handled correctly.
```

! Not all the named functions are defined for all three multiple precision derived types, so the
! list below shows which can be used. The labels "real", "integer", and "complex" refer to types
! FM, IM, and ZM respectively, "string" means the function accepts character strings (e.g.,
! TO_FM('3.45')), and "other" means the function can accept any of the machine precision data
! types integer, real, double, complex, or complex double. For functions that accept two or more
! arguments, like ATAN2 or MAX, all the arguments must be of the same type.

! Note that TO_ZM also has a 2-argument form: TO_ZM(2,3) for getting $2 + 3i$.
! CMPLX can be used for that, as in CMPLX(TO_FM(2) , TO_FM(3)), but the 2-argument form is
! more concise. The 2-argument form is available for machine precision integer, single and
! double precision real pairs. For others, such as X and Y being type(fm), just use CMPLX(X,Y).

! Fortran's 2-argument version of atan(x,y) is also provided. It is the same as the older atan2.
! Functions in this list that are not provided by standard Fortran, such as special functions,
! have more information about their arguments farther down.

! AVAILABLE FUNCTIONS:

```
! =
! +
! -
! *
! /
! **
! ==
! /=
! <
! <=
! >
! >=
! ABS          real      integer  complex

! SUBROUTINES THAT DO NOT CORRESPOND TO ANY FUNCTION ABOVE:

```

! 1. Type (FM).  MA, MB, MC refer to type (FM) numbers.

! FM_COSH_SINH(MA,MB,MC)    MB = COSH(MA),  MC = SINH(MA)
!                           Faster than making two separate calls.

! FM_COS_SIN(MA,MB,MC)    MB = COS(MA),  MC = SIN(MA)
!                           Faster than making two separate calls.

! FM_EULER(MA)            MA = Euler's constant ( 0.5772156649... )

! FM_FLAG(K)              K = KFLAG  get the value of the FM condition flag -- stored in
!                           the internal FM variable KFLAG in module FMVALS.

! FM_FORM(FORM,MA,STRING) MA is converted to a character string using format FORM and
!                           returned in STRING.  FORM can represent I, F, E, or ES formats.
!                           Example:
!                           CALL FMFORM('F60.40',MA,STRING)

! FM_FPRINT(FORM,MA)      Print MA on unit KW using FORM format.

! FM_PI(MA)               MA = pi

! FM_PRINT(MA)            Print MA on unit KW using current format.

! FM_RANDOM_NUMBER(X)     X is returned as a double precision random number, uniformly
!                           distributed on the open interval (0,1).  It is a high-quality,
!                           long-period generator based on 49-digit prime numbers.
!                           Note that X is double precision, unlike the similar Fortran
!                           intrinsic random number routine, which can return a single
!                           or double precision result.
!                           A default initial seed is used if FM_RANDOM_NUMBER is called
!                           without calling FM_RANDOM_SEED_PUT first.

! FM_RANDOM_SEED_GET(SEED) returns the seven integers SEED(1) through SEED(7) as the current
!                           seed for the FM_RANDOM_NUMBER generator.

! FM_RANDOM_SEED_PUT(SEED) initializes the FM_RANDOM_NUMBER generator using the seven integers
!                           SEED(1) through SEED(7).  These get and put functions are slower
!                           than FM_RANDOM_NUMBER, so FM_RANDOM_NUMBER should be called many
!                           times between FM_RANDOM_SEED_PUT calls.  Also, some generators that
!                           used a 9-digit modulus have failed randomness tests when used with
!                           only a few numbers being generated between calls to re-start with
!                           a new seed.

! FM_RANDOM_SEED_SIZE(SIZE) returns integer SIZE as the size of the SEED array used by the
!                           FM_RANDOM_NUMBER generator.  Currently, SIZE = 7.

! FM_RATIONAL_POWER(MA,K,J,MB)
!                           MB = MA**(K/J)  Rational power.
!                           Faster than MB = MA**(TO_FM(K)/J) for functions like the cube root.

! FM_READ(KREAD,MA)      MA is returned after reading one (possibly multi-line) FM number
!                           on unit KREAD.  This routine reads numbers written by FM_WRITE.

! FM_SET(NPREC)          Set the internal FM variables so that the precision is at least
!                           NPREC base 10 digits plus three base 10 guard digits.

! FM_SETVAR(STRING)     Define a new value for one of the internal FM variables in module

```

```

! ZM_COSH_SINH(MA,MB,MC)    MB = COSH(MA),  MC = SINH(MA).
!                               Faster than 2 calls.

! ZM_COS_SIN(MA,MB,MC)     MB = COS(MA),   MC = SIN(MA).
!                               Faster than 2 calls.

! ZM_FORM(FORM1,FORM2,MA,STRING)
!                               STRING = MA
!                               MA is converted to a character string using format FORM1 for the
!                               real part and FORM2 for the imaginary part.  The result is returned
!                               in STRING.  FORM1 and FORM2 can represent I, F, E, or ES formats.
!                               Example:
!                               CALL ZMFORM('F20.10','F15.10',MA,STRING)

! ZM_FPRINT(FORM1,FORM2,MA)  Print MA on unit KW using formats FORM1 and FORM2.

! ZM_PRINT(MA)               Print MA on unit KW using current format.

! ZM_READ(KREAD,MA)         MA is returned after reading one (possibly multi-line) ZM number
!                               on unit KREAD.  This routine reads numbers written by ZMWRITE.

! ZM_RATIONAL_POWER(MA,IVAL,JVAL,MB)
!                               MB = MA ** (IVAL/JVAL)
!                               Faster than MB = MA**(TO_FM(K)/J) for functions like the cube root.

! ZM_WRITE(KWRITE,MA)       Write MA on unit KWRITE.  Multi-line numbers are formatted for
!                               automatic reading with ZMREAD.

```

```

! Some other functions are defined that do not correspond to machine precision intrinsic
! functions.  These include formatting functions, integer modular functions and GCD, and some
! mathematical special functions.

```

```

! N, K below are machine precision integers, J1, J2, J3 are TYPE (IM), FMT, FMTR, FMTI are
! character strings, A, B, X are TYPE (FM), and Z is TYPE (ZM).

```

```

! The three formatting functions return a character string containing the formatted number, the
! three TYPE (IM) functions return a TYPE (IM) result, and the 12 special functions return
! TYPE (FM) results.

```

```

! Formatting functions:

```

```

! FM_FORMAT(FMT,A)          Put A into FMT (real) format
! IM_FORMAT(FMT,J1)         Put J1 into FMT (integer) format
! ZM_FORMAT(FMTR,FMTI,Z)    Put Z into (complex) format, FMTR for the real
!                               part and FMTI for the imaginary part

```

```

! Examples:

```

```

! ST = FM_FORMAT('F65.60',A)
! WRITE (*,*) ' A = ',TRIM(ST)
! ST = FM_FORMAT('E75.60',B)
! WRITE (*,*) ' B = ',ST(1:75)
! ST = IM_FORMAT('I50',J1)
! WRITE (*,*) ' J1 = ',ST(1:50)
! ST = ZM_FORMAT('F35.30','F30.25',Z)
! WRITE (*,*) ' Z = ',ST(1:70)

```

```

! These functions are used for one-line output.  The returned character strings are of
! length 200.

```

! For higher precision numbers, the output can be broken onto multiple lines automatically by calling subroutines FM_PRINT, IM_PRINT, ZM_PRINT, or the line breaks can be done by hand after calling one of the subroutines FM_FORM, IM_FORM, ZM_FORM.

! For ZM_FORMAT the length of the output is 5 more than the sum of the two field widths.

! Integer functions:

! BINOMIAL(N,K) Binomial coefficient N choose K. Returns the exact result as a
! type IM value.
! BINOMIAL(J1,J2) Binomial coefficient J1 choose J2. Like factorial below, the result
! might be too large unless min(J2,J1-J2) is fairly small,
! FACTORIAL(N) N! Returns the exact result as a type IM value.
! FACTORIAL(J1) J1! Note that the factorial function grows so rapidly that if type IM
! variable J1 is larger than the largest machine precision integer,
! then J1! has over 10 billion digits and the calculation would
! likely fail due to memory or time constraints. This version is
! provided for convenience, and will return UNKNOWN if J1 cannot
! be represented as a machine precision integer.
! GCD(J1,J2) Greatest Common Divisor of J1 and J2.
! MULTIPLY_MOD(J1,J2,J3) J1 * J2 mod J3
! POWER_MOD(J1,J2,J3) J1 ** J2 mod J3

! Special functions:

! BERNOULLI(N) Nth Bernoulli number
! BESSEL_J(N,X) Bessel function of the first kind J_n(x)
! BESSEL_J0(X) Fortran-08 name for J₀(x)
! BESSEL_J1(X) Fortran-08 name for J₁(x)
! BESSEL_JN(N,X) Fortran-08 name for J_n(x)
! BESSEL_JN(N1,N2,X) Returns array (/ J_{n1}(x) , ... , J_{n2}(x) /)
! BESSEL_Y(N,X) Bessel function of the second kind Y_n(x)
! BESSEL_Y0(X) Fortran-08 name for Y₀(x)
! BESSEL_Y1(X) Fortran-08 name for Y₁(x)
! BESSEL_YN(N,X) Fortran-08 name for Y_n(x)
! BESSEL_YN(N1,N2,X) Returns array (/ Y_{n1}(x) , ... , Y_{n2}(x) /)
! BETA(A,B) Integral (0 to 1) t^(a-1) * (1-t)^(b-1) dt
! BINOMIAL(A,B) Binomial Coefficient a! / (b! (a-b)!)
! COS_INTEGRAL(X) Cosine Integral Ci(x)
! COSH_INTEGRAL(X) Hyperbolic Cosine Integral Chi(x)
! ERF(X) Error function Erf(x)
! ERFCC(X) Complimentary error function Erfc(x)
! ERFCC_SCALED(X) Exp(x²) * Erfc(x)
! EXP_INTEGRAL_EI(X) Exponential Integral Ei(x)
! EXP_INTEGRAL_EN(N,X) Exponential Integral E_n(x)
! FACTORIAL(X) x! = Gamma(x+1)
! FRESNEL_C(X) Fresnel Cosine Integral C(x)
! FRESNEL_S(X) Fresnel Sine Integral S(x)
! GAMMA(X) Integral (0 to infinity) t^(x-1) * exp(-t) dt
! INCOMPLETE_BETA(X,A,B) Integral (0 to x) t^(a-1) * (1-t)^(b-1) dt
! INCOMPLETE_GAMMA1(A,X) Integral (0 to x) t^(a-1) * exp(-t) dt
! INCOMPLETE_GAMMA2(A,X) Integral (x to infinity) t^(a-1) * exp(-t) dt
! LOG_ERFC(X) Ln(Erfc(x))
! LOG_GAMMA(X) Analytic continuation of real Ln(Gamma(x)). May differ from complex
! Ln(Gamma(x)) by an integer multiple of 2*pi*i.
! LOG_INTEGRAL(X) Logarithmic Integral Li(x)
! POCHHAMMER(X,N) x*(x+1)*(x+2)*...*(x+n-1)

```

! POLYGAMMA(N,X)      Nth derivative of Psi(x)
! PSI(X)              Derivative of Ln(Gamma(x))
! SIN_INTEGRAL(X)    Sine Integral Si(x)
! SINH_INTEGRAL(X)   Hyperbolic Sine Integral Shi(x)

```

```

! Array operations:

```

```

! Arithmetic operations and functions on arrays of dimension (rank) one or two are supported for
! each of the three multiple-precision types. Binary operations (+-*/) require both arguments to
! have the same rank and shape.

```

```

! Examples:

```

```

! TYPE (FM), SAVE, DIMENSION(10) :: A, B
! TYPE (FM), SAVE, DIMENSION(3,3) :: C
! TYPE (IM), SAVE, DIMENSION(10) :: J, K
! TYPE (IM), SAVE, DIMENSION(3,3) :: L
!
! ...
! A = 0                ! Set the whole array to zero
! J = J * K           ! Set J(i) = J(i) * K(i) for i = 1, ..., 10
! B = A - K           ! Mixed-mode operations are ok
! C = 7.3D0 * C - ( C + 2*L )/3

```

```

! Array functions:

```

```

! DOT_PRODUCT(X,Y)    Dot product of rank 1 vectors of the same type.
!                    Note that when X and Y are complex, the result is not just the sum
!                    of the products of the corresponding array elements, as it is for
!                    types FM and IM. For ZM the formula is the sum of
!                    conjg(X(j)) * Y(j).
! IS_OVERFLOW(X)      Returns true if any element is + or - overflow.
! IS_UNDERFLOW(X)    Returns true if any element is + or - underflow.
! IS_UNKNOWN(X)       Returns true if any element is unknown.
! MATMUL(X,Y)         Matrix multiplication of arrays of the same type
!                    Cases for valid argument shapes:
!                    (1) (n,m) * (m,k) --> (n,k)
!                    (2) (m) * (m,k) --> (k)
!                    (3) (n,m) * (m) --> (n)
! MAXLOC(X)           Location of the maximum value in the array
! MAXVAL(X)           Maximum value in the array
! MINLOC(X)           Location of the minimum value in the array
! MINVAL(X)           Minimum value in the array
! PRODUCT(X)          Product of all values in the array
! SUM(X)              Sum of all values in the array
! TRANSPOSE(X)        Matrix transposition. If X is a rank 2 array with shape (n,m), then
!                    Y = TRANSPOSE(X) has shape (m,n) with Y(i,j) = X(j,i).
! TO_FM(X)            Rank 1 or 2 arrays are converted to similar type (fm) arrays.
! TO_IM(X)            Rank 1 or 2 arrays are converted to similar type (im) arrays.
! TO_ZM(X)            Rank 1 or 2 arrays are converted to similar type (zm) arrays.
! TO_INT(X)           Rank 1 or 2 arrays are converted to similar integer arrays.
! TO_SP(X)            Rank 1 or 2 arrays are converted to similar single precision arrays.
! TO_DP(X)            Rank 1 or 2 arrays are converted to similar double precision arrays.
! TO_SPZ(X)           Rank 1 or 2 arrays are converted to similar single complex arrays.
! TO_DPZ(X)           Rank 1 or 2 arrays are converted to similar double complex arrays.

```

```

! The arithmetic array functions DOT_PRODUCT, MATMUL, PRODUCT, and SUM work like the other
! functions in the FM package in that they raise precision and compute the sums and/or products
! at the higher precision, then round the final result back to the user's precision to provide

```

! a more accurate result.

! Fortran's optional [,mask] argument for these functions is not provided.

! Many of the 1-argument functions can be used with array arguments, with the result being an
! array of the same size and shape where the function has been applied to each element.

! Examples:

! TYPE (FM), SAVE, DIMENSION(10) :: A, B, C

! ...

! A = ABS(B) ! Set A(i) = ABS(B(i)) for i = 1, ..., 10

! C = SQRT(A+4*B*B) ! Set C(i) = SQRT(A(i)+4*B(i)*B(i)) for i = 1, ..., 10

! Functions that can have array arguments. As above, "real", "integer", and "complex" refer
! to types FM, IM, and ZM respectively.

! ABS	real	integer	complex	
! ACOS	real		complex	
! ACOSH	real		complex
